

1 BNF definition of PDDL 3.1

Hereby a complete BNF syntax definition of the PDDL 3.1 language is presented (completely corrected) based on the originally published articles and information about PDDL 1.2, 2.1, 2.2, 3.0 and 3.1 [1-5].

1.1 Domain description

```

<domain> ::= (define (domain <name>
                           [<require-def>]
                           [<types-def>] :typing
                           [<constants-def>]
                           [<predicates-def>]
                           [<functions-def>] :fluents
                           [<constraints>]
                           <structure-def>*))

<require-def> ::= (:requirements <require-key>*)
                  ::= See Section 1.3
<types-def> ::= (:types <typed list (name)>)

1.2 Problem description

1.2.1 Lifting restrictions (from constraint declaration)

If we wish to embed modal operators into each other, then we should use these rules instead of those in section 1.2 respectively.

```

<con-GD> ::= (always <con2-GD>)
<con-GD> ::= (sometime <con2-GD>)
<con-GD> ::= (within <number> <con2-GD>)
<con-GD> ::= (at-most-once <con2-GD>)
<con-GD> ::= (sometime-after <con2-GD> <con2-GD>)
<con-GD> ::= (sometime-before <con2-GD> <con2-GD>)
<con-GD> ::= (always-within <number> <con2-GD> <con2-GD>)
<con-GD> ::= (hold-during <number> <number> <con2-GD>)
<con-GD> ::= (hold-after <number> <con2-GD>)
<con2-GD> ::= <con-GD>
<con2-GD> ::= <GD>

```

1.3 Requirements

Here is a table of all requirements in PDDL3.1. Some requirements imply others; some are abbreviations for common sets of requirements. If a domain stipulates no requirements, it is assumed to declare a requirement for :strips.

:strips	Basic STRIPS-style adds and deletes
:typing	Allow type names in declarations of variables
:negative-preconditions	Allow <code>not</code> in goal descriptions
:disjunctive-preconditions	Allow <code>or</code> in goal descriptions
:equality	Support <code>=</code> as built-in predicate
:existential-preconditions	Allow <code>exists</code> in goal descriptions
:universal-preconditions	Allow <code>forall</code> in goal descriptions
:quantified-preconditions	<code>=</code> :existential-preconditions <code>+</code> :universal-preconditions
:conditional-effects	Allow <code>when</code> in action effects
:fluents	<code>=</code> :numeric-fluents <code>+</code> :object-fluents
:numeric-fluents	Allow numeric function definitions and use of effects using assignment operators and arithmetic preconditions.
:adl	<code>=</code> :strips <code>+</code> :typing <code>+</code> :negative-preconditions <code>+</code> :disjunctive-preconditions <code>+</code> :equality <code>+</code> :quantified-preconditions <code>+</code> :conditional-effects
:durative-actions	Allows durative actions. Note that this does not imply :numeric-fluents.
:duration-inequalities	Allows duration constraints in durative actions using inequalities.
:continuous-effects	Allows durative actions to affect fluents continuously over the duration of the actions.
:derived-predicates	Allows predicates whose truth value is defined by a formula
:timed-initial-literals	Allows the initial state to specify literals that will become true at a specified time point. Implies :durative-actions
:preferences	Allows use of preferences in action preconditions and goals.
:constraints	Allows use of constraints fields in domain and problem files. These may contain modal operators supporting trajectory constraints.
:action-costs	If this requirement is included in a PDDL specification, the use of numeric fluents is enabled (similar to the :numeric-fluents requirement). However, numeric fluents may only be used in certain very limited ways: <ol style="list-style-type: none"> 1. Numeric fluents may not be used in any conditions (preconditions, goal conditions, conditions of conditional effects, etc.). 2. A numeric fluent may only be used as the target of an effect if it is 0-ary and called <code>total-cost</code>. If such an effect is used, then the <code>total-cost</code> fluent must be explicitly initialized to 0 in the initial state. 3. The only allowable use of numeric fluents in effects is in effects of the form <code>(increase (total-cost) <numeric-term>)</code>, where the <code><numeric-term></code> is either a non-negative numeric constant or of the form <code>(<function-symbol> <term>*)</code>. (The <code><term></code> here is interpreted as shown in the PDDL grammar, i.e. it is a variable symbol or an object constant. Note that this <code><term></code> cannot be a <code><function-term></code>, even if the object fluents requirement is used.) 4. No numeric fluent may be initialized to a negative value. 5. If the problem contains a :metric specification, the objective must be <code>(minimize (total-cost))</code>, or - only if the :durative-actions requirement is also set - to minimize a linear combination of <code>total-cost</code> and <code>total-time</code>, with non-negative coefficients.
	Note that an action can have multiple effects that increase <code>(total-cost)</code> , which is particularly useful in the context of conditional effects.
	Also note that these restrictions imply that <code>(total-cost)</code> never decreases throughout plan execution, i.e., action costs are never negative.
